Systemic beta-blocker and nitrates result in a lowering of IOP which has implications for the management of ocular hypertension and glaucoma

The Science behind the Tip

Systemic beta-blockers and nitrates are frequently used in the elderly. It has been known for many years that systemic beta-blockers lower the IOP\(^1\). This was recently confirmed in a large population based, cross-sectional study\(^2\). Oral beta-blockers reduced the IOP by 1mmHg and systemic nitrates by 0.7mmHg on average, compared to those not using the medication, independently of age, gender or BMI. A difference of 1mmHg is relatively large at a population level and translates into a 14% reduced risk of incident glaucoma at 5 years for individuals on oral beta-blockers and a 10% reduced risk for those on nitrates\(^3\).

Although the concurrent prescription of oral and topical beta-blockers is not optimal practice it does occur very often in real life\(^4\). Therefore, the commencement or stopping of these systemic medications may have implications for the management of a known glaucoma patient as it may require an adjustment in the topical medication regimen.
